### ABSTRACT

The objective of this study was to evaluate the ability of several selection indices to identify drought tolerant/resistant genotypes under different conditions of Konya. Thirty six bread wheat genotypes (twenty four pure lines from Turkish bread wheat landraces and twelve modern bread wheat cultivars) were evaluated under both moisture stress (rainfed) and non stress (irrigated) conditions using a “randomized complete block design” with three replications. Nine drought tolerance indices including yield stability index (YSI), yield index (YI), superiority index ( $P_i$ ), stress tolerance index (STI), geometric mean productivity (GMP), stress susceptibility index (SSI), mean productivity (MP), stress tolerance (TOL), harmonic mean (HM) and linear regression coefficient ( $b_i$ ) were calculated. The indices were adjusted based on grain yield under drought condition ( $Y_s$ ) and normal conditions ( $Y_p$ ). SSI is suggested as useful indicator for wheat breeding where the stress is severe while MP, GMP, TOL HM and STI are suggested if the stress is less severe. Biplot analysis was used to explain relationship between grain yield and drought indices. Karahan-99, Bayraktar-2000, Gerek-79, PL-7, Sönmez-2000, Kırac-66 and PL-5 were the superior genotypes for both rainfed and irrigated conditions with high PC1 and low PC2. PL-25, PL-13 and PL-23 with high PC2 were more suitable for rainfed than irrigated conditions.

**Key words:** biplot analysis, drought indices, Turkey, winter bread wheat landraces.

### INTRODUCTION

Wheat is mainly grown on rain-fed land. About 70 % of the area of Turkey consists of semiarid environments in which available moisture constitutes a primary constraint in wheat production. Climatic variability in these marginal environments causes large annual fluctuations in grain yield.

Breeding for drought resistance is complicated by the lack of fast, reproducible screening techniques and the inability to routinely create defined and repeatable water stress conditions when a large amount of genotypes are to be evaluated efficiently (Ramirez and Kelly, 1998). Achieving a genetic increase in yield under these environments has been recognized to be a difficult challenge for plant breeders while progress in yield has been much higher in favorable environments (Richards *et al.*, 2002). Thus, drought indices which provide a measure of drought based on yield loss under drought conditions in comparison to normal conditions have been used for screening drought-tolerant genotypes (Mitra, 2001). Selection of wheat genotypes with better adaptation to water stress should increase the productivity of rainfed wheat (Rajaram, 2001).

The relative yield performance of genotypes in drought stressed and more favorable environments seems to be a common starting point in the identification of traits related to drought tolerance and the selection of genotypes for use in breeding for dry environments

(Clarke *et al.*, 1992). According to Fernandez (1992), genotypes can be divided into four groups based on their yield response to stress conditions: (1) genotypes producing high yield under both water stress and non-stress conditions (group A), (2) genotypes with high yield under non-stress (group B) or (3) stress (group C) conditions and (4) genotypes with poor performance under both stress and non-stress conditions (group D).

To differentiate drought resistant genotypes, several selection indices have been suggested on the basis of a mathematical relationship between favorable and stressed conditions (Clarke *et al.*, 1984; Huang, 2000). Tolerance (TOL) (McCaig and Clarke, 1982; Clarke *et al.*, 1992), mean productivity (MP) (McCaig and Clarke, 1982), stress susceptibility index (SSI) (Fischer and Maurer, 1978), harmonic mean (HM) (Chakherchaman *et al.*, 2009), geometric mean productivity (GMP) and stress tolerance index (STI) (Fernandez, 1992) All of these have been employed under various conditions. The superiority measure ( $P_i$ ) proposed by Lin and Binns (1988) is another indicator that compares the productivity of genotypes across different environments.

The objectives of the study were to (i) identify drought tolerant bread wheat genotype(s) under rainfed conditions in the Central Anatolian Region of Turkey, (ii) determine the efficiency of tolerance indices to classify both modern bread wheat cultivars and pure lines into sensitive and tolerant and (iii) study interrelationships among the tolerance indices.

## MATERIALS AND METHODS

The bread wheat selection and improvement program was initiated by screening landraces collected from different localities. In 2002, at least 82 populations were collected from the villages of Bozkır, Ahırlı, Hadim, Taşkent, and Seydişehir, where wheat landraces were still grown in small fields (0.005-0.05 ha) and farmers had been using their own seed for generations (Akçura, 2009). In the 2002-2005 growing seasons pure lines were selected in Konya province.

Twenty four pure lines and twelve cultivars (Gerek-79, Karahan-99, Bayraktar-2000, Dağdaş-94, Tosunbey, Demir-2000, Bezostaja-1, Konya-2002, Sönmez-2000, Katea-1, Kıraç-66 and Köse 220/39) were chosen for the study based on their reputed differences in yield performance under irrigated and non-irrigated conditions. The origins of the selected pure lines, history of selection, and standard cultivars are given in Table 1.

Experiments were conducted at Bahri Dağdaş International Agricultural Research Institute, in Konya province (Central Anatolian Region of Turkey) in 2006-2007 and 2007-2008 growing seasons. Experimental layout was a "randomized complete blocks design" with three replications in both rainfed and irrigation conditions. Sowing was done by an experimental drill in 1.2 m x 7 m plots, consisting of six rows with 20 cm apart. For irrigated plots, 50 mm of water were applied at both tillering and booting stage. Non-irrigated plots were grown under rainfed conditions. Sowing was done in October. Seed density was 550 seeds m<sup>-2</sup> under rainfed conditions and 500 seeds m<sup>-2</sup> under irrigated conditions (Akçura, 2011). The plots were fertilized with 27 kg N ha<sup>-1</sup> and 69 kg P<sub>2</sub>O<sub>5</sub> ha<sup>-1</sup> at planting and 40 kg N ha<sup>-1</sup> at the stem elongation. Crop plots (1.2 m x 5 m) were harvested by a combined plot harvester.

The experiments were performed in a clay-loam soil with a pH of 7.7 under rain fed and irrigated conditions in 2006-2007 and 2007-2008 growing seasons.

The total mean rainfall during the two growing seasons in Konya (Latitude: 37°51'43" N; Longitude: 32°33'31"E; Altitude: 1009 m above sea level) was 248 and 311 mm, respectively. The amounts were lower than the long-term rainfall for Konya (320 mm).

The grain yield (GY) was determined and expressed as ton per hectare (t ha<sup>-1</sup>). Data on other yield related traits were also recorded viz., number of spike m<sup>-2</sup> (NS), number of grains m<sup>-2</sup> (NG), weight of grains spike<sup>-1</sup> (g) (WGS), number of grains spike<sup>-1</sup> (NGS), plant height (cm) (PH).

Drought resistance indices were calculated using the following relationships:

1. Yield stability index (YSI) =  $\frac{Y_S}{Y_P}$  (Bouslama and Schapaugh, 1984).

2. Superiority index (P<sub>i</sub>) =  $\sum_{j=1}^n \frac{(X_{ij}-M_j)^2}{2n}$  (Clarke *et al.*, 1992).

where n is the number of environments, X<sub>ij</sub> the grain yield of ith genotype in the jth environment and M<sub>j</sub> is the yield of the genotype with maximum yield at environment j.

3. Yield index (YI) =  $\frac{Y_S}{Y_P}$  (Gavuzzi *et al.*, 1997).

4. Stress tolerance index (STI) =  $\frac{Y_P+Y_S}{\bar{Y}_P}$  (Fernandez, 1992).

5. Geometric mean productivity (GMP) =  $\sqrt{(Y_P \times Y_S)}$  (Fernandez, 1992).

6. Stress susceptibility index (SSI) =  $\frac{1 - (\frac{Y_S}{Y_P})}{1 - (\frac{Y_S}{\bar{Y}_P})}$  (Fischer and Maurer, 1978)

7. Mean productivity (MP) =  $\frac{Y_P+Y_S}{2}$  (Hossain *et al.*, 1990).

8. Stress tolerance (TOL) =  $Y_P - Y_S$  (Hossain *et al.*, 1990).

Harmonic mean (HM) =  $\frac{2(Y_P \times Y_S)}{(Y_P+Y_S)}$  (Chakherchaman *et al.*, 2009).

10. Linear regression coefficient (b<sub>1</sub>): The coefficient of linear regression of grain yield of a cultivar in each environment on the environmental index (mean yield of all cultivars at any environment) (Bansal and Sinha, 1991).

Combined analysis of variance, correlation and biplot analyses were carried out using SAS, version 9.0 (SAS Institute, 1999).

## RESULTS

The results of analysis of variance for GY, PH, NG, NS, WGS and NGS are presented in Table 2. Among the genotypes, significant differences were observed for all investigated characters (Table 2).

The main effect of moisture regimes and the interaction between genotypes x moisture regimes were highly significant for the measured traits. Grain yield and studied traits of genotypes varied, particularly under stress conditions, year by year (Table 3 and 4). Drought stress significantly decreased GY, PH, NG, NS, WGS and NGS (Table 3 and 4).

Grain yields of rainfed conditions ranged between 1.06 and 2.12 t ha<sup>-1</sup> and of irrigated conditions between 2.73 and 5.73 t ha<sup>-1</sup> (Table 3). Mean grain yield in rainfed conditions was 58% smaller than in irrigated

conditions. The mean yield of 12 bread wheat cultivars under rain fed and irrigated conditions were 1.64 and 4.65 t ha<sup>-1</sup>, respectively (Table 3). For pure lines, mean grain yield under rainfed and irrigated conditions were 1.84 and 3.57 t ha<sup>-1</sup>, respectively (Table 3). The mean grain yield of cultivars and pure lines was reduced (64% and 48%, respectively) under rainfed conditions (Table 3).

Karahan-99, Bayraktar-2000 and Gerek-79 were the most productive cultivars in irrigated and the least productive one in rainfed conditions. For the pure lines, PL-7 and PL-5 had the highest grain yield in irrigated

environment. In rainfed conditions, PL-18 and PL-13 pure lines produced the highest and second highest grain yields of 2.12 t ha<sup>-1</sup> and 2.06 t ha<sup>-1</sup>, respectively (Table 3).

As shown in Table 5, the greater the TOL value, the larger the yield reduction under stress condition and the higher the drought sensitivity. A positive correlation between irrigated yield (GY<sub>IRR</sub>) and SSI, TOL and a negative correlation between grain yield of rainfed (GY<sub>NIR</sub>) and SSI, TOL (Table 6) suggest that selection based on SSI and TOL will result in reduced yield under irrigated conditions. Especially, negative correlation between SSI and GY<sub>NIR</sub> was expected because

**Table 4. Studied Traits of bread wheat genotypes (averaged over 2 years)**

GY: grain yield, :NS number of spike m<sup>-2</sup>, NG: number of grain m<sup>-2</sup>, WGS: weight of grains spike<sup>-1</sup>, NGS: number of grain spike<sup>-1</sup>, PH: plant height.

genotypes that suffer less yield loss from irrigated to rainfed conditions also tend to have high yield in stress environments. SSI identified some genotypes such as Köse 220/39, Katea-1 and PL-7 as stress resistant though they did not have outstanding yield performance in stress primarily because of their low potential yield (Table 3). Thus, genotypes with the lowest yield under irrigated conditions exhibited the highest P<sub>i</sub> value. This is confirmed by a negative and significant correlation between P<sub>i</sub> and yield under non-stress conditions (Table 6). On the other hand, the association between P<sub>i</sub> and yield under stress was non significant. Selection based on

YSI and P<sub>i</sub> value will result in increased yield under irrigated conditions. SSI showed a negative correlation with yield under rain fed conditions, while showed a positive correlation with yield under irrigated conditions (Table 6). YI, YSI, STI, GMP, MP and HM were significantly and positively correlated with stress yield. These indices showed that cultivars may be ranked only on the basis of their yield under stress (Tables 3) and so does not discriminate genotypes of group A. conditions. The mean yield of 12 bread wheat cultivars under rain fed and irrigated conditions were 1.64 and 4.65 t ha<sup>-1</sup>, respectively (Table 3). For pure lines, mean

**Table 5. Resistance indices of 36 bread wheat genotypes (averaged over 2 years)**

\*: P ≤ 0.05, \*\*: P ≤ 0.01, GY: grain yield, :NS number of spike m<sup>-2</sup>, NG: number of grain m<sup>-2</sup>, WGS: weight of grains spike<sup>-1</sup>, NGS: number of grain spike<sup>-1</sup>, PH: plant height.

grain yield under rainfed and irrigated conditions were 1.84 and 3.57 t ha<sup>-1</sup>, respectively (Table 3). The mean grain yield of cultivars and pure lines was reduced (64% and 48%, respectively) under rainfed conditions (Table 3).

Karahan-99, Bayraktar-2000 and Gerek-79 were the most productive cultivars in irrigated and the least productive one in rainfed conditions. For the pure lines, PL-7 and PL-5 had the highest grain yield in irrigated environment. In rainfed conditions, PL-18 and PL-13 pure lines produced the highest and second highest grain yields of 2.12 t ha<sup>-1</sup> and 2.06 t ha<sup>-1</sup>, respectively (Table 3).

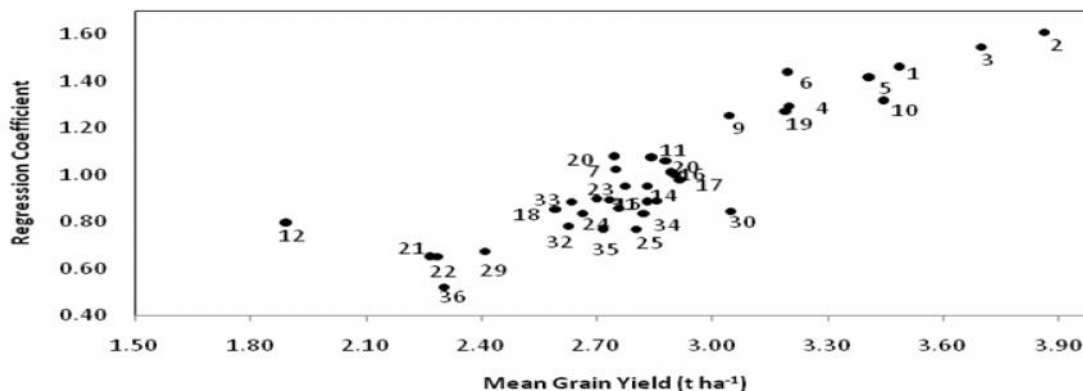

As shown in Table 5, the greater the TOL value, the larger the yield reduction under stress condition and the higher the drought sensitivity. A positive correlation between irrigated yield (GY<sub>IR</sub>) and SSI, TOL and a negative correlation between grain yield of rainfed (GY<sub>NIR</sub>) and SSI, TOL (Table 6) suggest that selection based on SSI and TOL will result in reduced yield under irrigated conditions. Especially, negative correlation between SSI and GY<sub>NIR</sub> was expected because genotypes

that suffer less yield loss from irrigated to rainfed conditions also tend to have high yield in stress environments. SSI identified some genotypes such as Köse 220/39, Katea-1 and PL-7 as stress resistant though they did not have outstanding yield performance in stress primarily because of their low potential yield (Table 3). Thus, genotypes with the lowest yield under irrigated conditions exhibited the highest P<sub>i</sub> value. This is confirmed by a negative and significant correlation between P<sub>i</sub> and yield under non-stress conditions (Table 6). On the other hand, the association between P<sub>i</sub> and yield under stress was non significant. Selection based on YSI and P<sub>i</sub> value will result in increased yield under irrigated conditions. SSI showed a negative correlation with yield under rain fed conditions, while showed a positive correlation with yield under irrigated conditions (Table 6). YI, YSI, STI, GMP, MP and HM were significantly and positively correlated with stress yield. These indices showed that cultivars may be ranked only on the basis of their yield under stress (Tables 3) and so does not discriminate genotypes of group A.

**Figure 2. Plot of the variance between the regression coefficients against mean grain yield (t ha<sup>-1</sup>) for 36 bread wheat genotypes over environments.**

## DISCUSSION

There is general agreement that modern high yielding wheat cultivars are more adapted to favorable growing conditions, while old cultivars and landraces have more stable yield under drought stress conditions (Ceccarelli and Grando, 1991; Blum, 1996, Mardeh *et al.*, 2006). Ceccarelli (1989) reported a 25– 61% superiority of landraces over modern genotypes under stress conditions and 6–18% superiority of modern genotypes over landraces under non-stress conditions. In the study, it was observed a higher superiority of landraces over modern genotypes under stress conditions with a maximum of 11% and lower superiority of modern genotypes to landraces under non-stress conditions with a maximum of 23% (Table 3).

The poor yielding cultivars/pure lines in the present study were tall, sensitive to lodging, and with low NGS and NG, the desirable traits for rainfed condition but undesirable for irrigated condition (Mardeh *et al.*, 2006). The reason for lower grain yield under rainfed condition was mainly due to a reduction in NS and NG. The NG in rainfed condition was lower about 36% than in irrigated condition. The average NS in rainfed and irrigated conditions was 428.5 and 619.4, respectively (Table 4). Several studies indicated that semi dwarf stature is preferred in late season drought condition (Fischer and Maurer, 1978; Richards, 1996; Van Ginkel *et al.*, 1998). Van Ginkel *et al.*, (1998) also found that many NGS was critical to high yield only in irrigated condition and it was negatively correlated with yield under late season drought condition. Also, water deficit occurred from anthesis to maturity, and this usually results in poor assimilation, reduced translocation of photosynthates to the grain and higher respiratory losses (Al-Khatib and Paulsen, 1984; Acevedo, 1990; Shpiler and Blum, 1991). Consequently, the effect of drought stress was manifested in lower number and weight of kernels per spike as in grain yield (Table 4).

Biplot analysis revealed that the first PCA explained 70.0% of the variation with Yp, MP, GMP and STI (Figure 1). Thus, the first dimension can be named as the yield potential and drought tolerance. Considering the high and positive value of this PCA on biplot, selected genotypes will be high yielding under rain-fed and irrigated environments. The second PCA explained 29% of the total variability and had positive correlation with Ys, YI and YSI. Therefore, the second component can be named as a stress-tolerant dimension and it separates the stress-tolerant genotypes from non-stress tolerant ones. Thus, selection of genotypes that have high PCA1 and low PCA2 are suitable for both rain-fed and irrigated conditions. Therefore, Karahan-99, Bayraktar-2000, Gerek-79, PL-7, Sönmez-2000, Kırac-66 and PL-5 are the superior genotypes for both rainfed and irrigated conditions with high PC1 and low PC2. PL-25, PL-13

and PL-23 with high PC2 were more suitable for rain-fed than irrigated conditions.

It was interesting to note positive correlation between SSI and Yp indicating that stress susceptibility was positively correlated with non-stressed yield (Fischer and Wood 1979; Ceccarelli and Grando, 1991). This suggested that some characteristics that contribute to yield potential may act to increase susceptibility to stress and that selection for both SSI and Yp may counteract each other. However, Ehdaie and Shakiba, (1996) in wheat found that there was no correlation between stress susceptibility and yield under optimum environments.

The STI, GMP and MP were used for screening drought tolerant high yielding genotypes in the both conditions (Fernandez, 1992; Mohammadi *et al.*, 2003; Mohammadi *et al.*, 2010). These parameters under level of high to moderate stress were correlated (indicate -ve or +ve) with yield under both conditions (Table 6). For this reason, MP also were reported by Fernandez (1992) who was able to differentiate genotypes belong to A-group (including genotypes with high yield performance in both conditions, from the others (B, C or D groups). MP is related to yield under drought stress if it is not too severe and the difference between YR and YI is not too large. In these cases, genotypes with a high MP would belong to A-group (Mohammadi *et al.*, 2010). When the stress was severe, SSI were found to be more useful indices discriminating resistant genotypes, although none of the indicators could clearly identify cultivars with high yield under both rain-fed and irrigated conditions.

Modern bread wheat cultivars e.g. Karahan-99, Bayraktar-2000, Gerek-79 and Dağdaş-94 had larger b<sub>1</sub> values indicating greater sensitivity to environmental change. They were relatively better in favorable environments, but less adapted to low yielding environments than pure lines PL-23 and PL-18. The inability of these cultivars (Karahana-99 and Bayraktar-2000) to maintain yield under poor growing conditions may presumably be because of their lesser ability to tolerate stresses relative to others (Figure 2).

The use of bread wheat landraces has been neglected in bread wheat breeding programmes in Turkey on the basis that they have low-yield potential under irrigated conditions. There is general agreement that modern high-yielding cultivars are more adapted to favourable growing conditions while landraces have usually out yielded the exotic material under low input conditions (Blum, 1988; Ceccarelli and Grando, 1991; Dencic *et al.*, 2000; Akçura, 2011). Ceccarelli *et al.*, (1998) claimed that the most effective way to improve the productivity of crops grown in less-favourable areas is to use locally adapted germplasm and select form target environments. The drought conditions are predominant over the years and wet years are infrequent in the Central Anatolian Region of Turkey. Thus, selection should be based on the yield in the target

environments as Ceccarelli (1987), Ceccarelli and Grando (1991) and Rathjen (1994) have suggested.

If the strategy of breeding program is to improve yield in a small stress or non-stress environment, it may be possible to explain local adaptation to increase gains from selection conducted directly in that environment (Atlin *et al.*, 2000; Hohls, 2001; Mardeh *et al.*, 2006). The findings of this study showed that the breeders should choose the indices on the basis of stress severity in the target environment. SSI is suggested as useful indicator for wheat breeding, where the stress is severe while MP, GMP, TOL HM and STI are suggested if the stress is less severe.
